1. Introduction

The *PersistenceBroker API (PB-api)* provides the lowest level access to OJB's persistence engine. While it is a low-level API compared to the standardised ODMG or JDO API's it is still very straightforward to use.

The core class in the PersistenceBroker API is the `org.apache.ojb.broker.PersistenceBroker` (../../api/org/apache/ojb/broker/PersistenceBroker.html) class. This class provides the point of access for all persistence operations in this API.

This document is not a PB tutorial (../../docu/tutorials/pb-tutorial.html) (newbies please read the tutorial first) rather than a guide showing the specific usage and possible pitfalls in handling the PB-api.

If you don't find an answer for a specific question, please have a look at the FAQ (../../docu/faq.html) and the other reference guides (../../docu/guides/summary.html) .

2. How to access the PB-api?

The `org.apache.ojb.broker.PersistenceBrokerFactory` make several methods available:

```
public PersistenceBroker createPersistenceBroker(PBKey key) throws
PBFactoryException;

public PersistenceBroker createPersistenceBroker(String jcdAlias, String
user, String password)
    throws PBFactoryException;

public PersistenceBroker defaultPersistenceBroker() throws
PBFactoryException;
```

Method `defaultPersistenceBroker()` can be used if the attribute *default-connection* (../../docu/guides/repository.html#jdbc-connection-descriptor) is set *true* in *jdbc-connection-descriptor*. It's a convenience method, useful when only one database is used.

The standard way to lookup a broker instance is via `org.apache.ojb.broker.PBKey` by specify *jcdAlias* (defined in the *jdbc-connection-descriptor* of the repository file or sub file (../../repository_database.xml.txt)), *user* and *passwd*. If the user and password is already set in *jdbc-connection-descriptor* it is possible to lookup the broker instance only be specify the *jcdAlias* in PBKey:

```
PBKey pbKey = new PBKey("myJcdAliasName", "user", "password");
// alternative if user/passwd set in configuration file
PBKey pbKey = new PBKey("myJcdAliasName");
PersistenceBroker broker =
PersitenceBrokerFactory.createPersistenceBroker(pbKey);
```

See further in FAQ "Needed to put user/password of database connection in repository file?" (../../docu/faq.html#userPasswordNeeded) .

3. Notes on Using the PersistenceBroker API

3.1. Exception Handling

The exception handling is described in the PB-tutorial exception handling section (../../docu/tutorials/pb-tutorial.html#exception-handling) .

3.2. Management of PersistenceBroker instances

There is no need to cache or pool the used PersistenceBroker (../../api/org/apache/ojb/broker/PersistenceBroker.html) instances, because OJB itself use a PB-pool. The configuration of the PB-pool is adjustable in the OJB.properties (../../OJB.properties.txt) file.

Using the `PersistenceBroker.close()` method releases the broker back to the pool under the default implementation. For this reason the examples in the PB tutorial (../../docu/tutorials/pb-tutorial.html) all retrieve, use, and close a new broker for each logical transaction.

Apart from the pooling management `PersistenceBroker.close()` force the internal cleanup of the used broker instance - e.g. removing of temporary PersistenceBrokerListener instances, release of used connection if needed, internal used object registration lists, ... Therefore it's not recommended always refer to the same PB instance without closing it.

3.3. Transactions

Transactions in the PeristenceBroker API are *database level transactions*. This differs from *object level transactions* used by e.g. the odmg-api (../../docu/guides/odmg-guide.html) . The broker does not maintain a collection of modified, created, or deleted objects until a commit is called -- it operates on the database using the databases transaction mechanism. If object level transactions are required, one of the higher level API's (ODMG, JDO, or OTM) should be used.
